Abstract

This article examines social science relevant to public engagements and identifies the challenges to the goal of meaningful public input into science and technology policy. Specifically, when considering “which forms, features, and conditions of public engagement are optimal for what purposes, and why?” we find social science has not clarified matters. We offer a model to guide systematic research that defines and empirically connects variations in features and types of public engagement activities to specifically defined variations in effective processes and outcomes. The specification of models, as we have done, will guide policy makers, practitioners, and the public in determining what kinds of engagement techniques are optimal for what kinds of purposes. Our model is presented to start conversations and inspire research that in the future should help to ensure meaningful public participation that meets the promise of contributing thoughtful societal values and perspectives into governmental policies impacting science and technology research.

KEY WORDS: public engagement, science and technology policy

Public engagement is a valuable means to provide societal perspectives concerning the policy, legal, ethical, and other impacts of scientific and technological research. Input from the public has been provided via such methods as surveys, legislative hearings, public meetings, and notice and comment opportunities. In recent decades, more interactive public engagements, involving residents, scientists, and policy makers, have been convened to help shape science and technology policy. These approaches, including citizen juries, consensus conferences, and citizen deliberations (see generally, Delli Carpini, Cook, & Jacobs, 2004), have been applauded for giving the public a more meaningful role in shaping science and technology policy while, at the same time, castigated for not really engaging the

public (e.g., Fiorino, 1990; Lewenstein & Brossard, 2006; Rowe & Frewer, 2000, 2005). For example, it has been argued the engagements often do not take place early enough in the decision-making process, and the impacts of public inputs on policy outputs are unclear and uncertain (Wilsdon & Willis, 2004).

To achieve the objective of meaningful and influential public input to the policy-making process related to science and technology, public engagements must be effective for that purpose. However, the public engagement social science literature has provided little systematic guidance for selecting which public engagement methods to use for which purposes. There are numerous public engagement methods available to use, and the costs associated with them vary considerably. Town hall meetings, for example, are quite inexpensive, but perhaps they are not as useful for helping inform policy. Most agree the public input obtained from town hall meetings across the United States on health-care reform in the summer of 2009 provided little policy-relevant information (Collins, 2009; Urbina, 2009; Urbina & Seelye, 2009). On the other hand, there is no empirical evidence that a different kind of public input forum (see generally, Mitton, Smith, Peacock, Evoy, & Abelson, 2009) would have provided a more nuanced sense of the public's policy (as opposed to political) preferences or that more useful policy information would have been adduced had more expensive and carefully planned public engagements been conducted (see, e.g., Littlejohns & Rawlins, 2009).

Thus, in spite of the widespread perceived importance of public engagement in policy making, in general, and for science and technology policy in particular, there is a serious gap in scientific knowledge concerning *which* forms or features of public engagement, and conditions for such engagements, will result in *effective* engagements, that is, engagements that are meaningful to participants and produce information and insights useful both to scientists and policy makers. The field lacks theoretical models that will advance research and guide practitioners in their design of public engagement activities. Lack of such models and guidance has resulted in public engagements that sometimes have negative effects, resulting in outcomes such as group conflict, polarization, dissatisfaction among participants, or the failure to obtain public input that benefits policy (e.g., Delli Carpini et al., 2004; Sunstein, 2005).

We explore the possibilities of public engagements to inform science and innovation policy in the context of *nanotechnology*. We examine the social science literature relevant to nanotechnology public engagements in order to identify and assess the challenges that confront the goal of and meaningful public input. These challenges can be summarized as stemming from the lack of an answer to the question of *which* forms, features, and conditions of public engagement are optimal for *what* purposes, and *why*?

Although the focus of our article is on nanotechnology, the issues raised are applicable to not only science and technology issues but also to public engagement related to policy making in virtually any context. Further, although the majority of our focus in this article is on practices in the United States and Europe, public engagements concerning nanotechnology have been conducted, and continue to take place, across the globe (e.g., *Australia*: Cormick, 2009; Department of Innovation, Industry, Science and Research, Australian Government, 2010; Katz, Lovel, Mee, & Solomon, 2005; Kyle & Dodds, 2009; Solomon, Katz, Lovel, & Mee, 2005;

Brazil: Macnaghten & Guivant, in press; *India*: The Energy and Resources Institute [TERI], 2009, 2010; *South Africa*: South African Agency for Science and Technology Advancement, 2010; *Zimbabwe*: Grimshaw, Stilgoe, & Gudza, 2006). Indeed, since 2003, there have been more than 100 major engagement activities focused on nanotechnology across the globe (e.g., Center for Nanotechnology in Society, 2010; Department of Innovation, Industry, Science and Research, Australian Government, 2010; European Commission, 2009; see generally, Laffite & Joly, 2008).

Public Engagement and Nanotechnology

Conceptually, the interest in the American public's input into science and technology policy is part of the greater issue of open and transparent government (e.g., Brief Amicus Curiae in Support of Respondents Sierra Club and Judicial Watch, Inc., 2004; Brito, 2008; Fenster, 2006; Fung, Goldman, McCoy, & Wright, 2009; Holdren, 2010; Kundra & Noveck, 2009; National Academy of Public Administration, 2009; Obama, 2009; Office of Science and Technology Policy, 2010) and the democratic ideal (Dahl, 1994; Delli Carpini et al., 2004; Fishkin, 1991; Meadowcroft, 2004; Pateman, 1970; Verba & Nie, 1972). The specific idea that the public should weigh in on science and technology is of fairly recent vintage: Its roots trace back to the ethical lapses of scientists that resulted in Congress mandating stricter oversight of the conduct of science via institutional review boards that included citizen representatives (e.g., National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1979; Petersen, 1984; Rothman, 1991; Weisstub, 1998). The explicit purpose of including citizen representatives was to ensure that public values were included in scientific considerations. Basing its approach on the significant scientific, political, and societal successes of the ethics, law, and social implications [Ethical, Legal and Social Implications (ELSI)] initiative of the transformative human genome project of the 1990s (ELSI Research Program, 2009, and links therein), Congress provided for an even greater role for the public in its 21st Century Nanotechnology Research and Development Act (2003) (Sargent, 2010). The Nanotechnology Act calls for public participation in strategic decision making related to nanotechnology development, specifically, "the convening of regular and ongoing public discussions, through mechanisms such as citizens' panels, consensus conferences, and educational events, as appropriate" (§ 2(b)(10)).

Congress' decision to mandate public input for science and technology purposes was unprecedented in U.S. history (see, e.g., Jasanoff, 2003). Public engagement, Congress indicated, promises the possibility of interconnections among science, technology, and society, allowing science and society to shape one another, and providing a critical element for understanding the ethical, legal, and other societal "impacts of new technologies on individuals and society" (Ethical, Legal, and Other Societal Issues, n.d.). It is "vital in the nanotechnology R&D enterprise" (Societal Dimensions, n.d.) (see also Lewenstein, 2005; Roco, 2003).

The routine use of public engagement for general policy-making purposes, including but not limited to science and technology policy, has been commonplace in the United Kingdom since the Blair Administration (e.g., Better Regulation Executive, 2008; Council for Science and Technology, 2005; House of Lords, 2000). Public engagement also has been routinely utilized throughout the European

Union (e.g., European Commission, 2007a, 2007b, 2008; see generally European Commission, 2009; see also Hullmann, 2008; Involve, 2008; Kaufmann, Audétat, & Joseph, 2009; Macnaghten, Kearnes, & Wynne, 2005; Rogers-Hayden & Pidgeon, 2006) to focus on issues related to nanotechnology policy. Since 2003, there have been approximately 100 major engagement activities focused on nanotechnology in the United States and elsewhere around the world (Laffite & Joly, 2008; see generally, Center for Nanotechnology in Society, 2010; Department of Innovation, Industry, Science and Research, Australian Government, 2010; European Commission, 2009).

The engagements that have taken place have varied widely, covering the spectrum of public engagement opportunities and providing some useful initial information—both concerning nanotechnology and concerning the types of information that might be gleaned from different methods. For example, in their study of nanotechnology *focus group* conversations in the UK, Kearnes and Wynne (2007) found that many participants had an ambivalent attitude toward technological advances in general and not surprisingly, toward nanotechnology as well. In the United States, Hamlett, Cobb, and Guston (2008) conducted a series of six nanotechnology *consensus conferences* that confirmed the public's lack of sophisticated knowledge and ongoing concerns concerning nanotechnology (see also, Macoubrie, 2005; Solomon et al., 2005). *Opinion surveys*, in contrast, have shown more positive attitudes, particularly in instances in which people have higher levels of knowledge concerning the issues (Cobb & Macoubrie, 2004; Currall, King, Lane, Madera, & Turner, 2006; Scheufele & Lewenstein, 2005; Scheufele et al., 2007). Meanwhile, Pidgeon, Harthorn, Bryant, and Rogers-Hayden (2009) conducted four *deliberative workshops*, two in Santa Barbara and two in Cardiff and compared with survey methods, found more nuanced opinions concerning nanotechnology, including strong differences in public views concerning different nanotechnology applications (in health and energy domains) and subtle differences in United States versus British views. Finally, an *experimental study* by Kahan, Braman, Slovic, Gastil, and Cohen (2009) indicated risk versus benefit perceptions concerning nanotechnology vary depending on psychosocial variables such as cultural cognition and political characteristics.

In addition to the different findings associated with different participation methods, findings can differ *within* methods. To explain such differences, Rogers-Hayden and Pidgeon (2006), for example, suggested the *contextual framing* of participatory discussions may influence participants' ability to offer meaningful input (see also Kahan et al., 2009). They argued meaningful engagement of the public concerning nanotechnology entails moving beyond discussions focused on risk to broader, less tangible topics concerning values and governance. Engagement or deliberation *process details* may also influence perceptions concerning nanotechnologies. Hamlett and Cobb (2006) utilized small-scale discussions concerning nanotechnology based on the consensus conference model. Though they were specifically examining potential opinion polarization, they noted that discussion facilitation, composition of educational materials, interaction with experts, and the selection process of experts can impact quality of discussion and participants' opinions.

Taken together, the varied and often disparate findings within the public participation in nanotechnology literature suggest the vital importance of understanding which types or features of participation activities lead to what out-

comes and why. Without such understanding, it is difficult to interpret the findings from any given engagement. For example, what should policy makers weigh more heavily: positive views concerning nanotechnology expressed in one engagement context or more cautious or negative views expressed in another? Although, as reviewed earlier, some preliminary associations between features and outputs have been noted, there is little theoretical guidance to explain contradictory results that have been obtained (e.g., Brossard & Lewenstein, 2009; Cobb & Macoubrie, 2004; Currall et al., 2006; Davies, 2009; Hamlett et al., 2008; Scheufele & Lewenstein, 2005; Scheufele et al., 2007), and there is little in the way of theoretically driven, systematic, and experimental investigations of the effects of varied features of public engagements that would provide data for building theoretical models that would help explain how to maximize desired processes and outcomes (see Currall, 2009). This is not peculiar to the nanotechnology context: there have been few attempts to systematically vary critical elements of engagement techniques to study their impacts, a significant gap in the field (Delli Carpini et al., 2004).

Public Engagement Social Science: Current Status and Future Directions

There is a critical dearth of scientific knowledge across the disciplines that study engagements concerning *which* forms, features, and conditions are optimal for *what* purposes and *why*. This gap manifests itself in models of public engagements that are disconnected from empirical evidence, that are too general to guide decisions concerning public engagement in specific contexts or for specific purposes, and that fail to adequately explain why public engagement outcomes differ across studies. Currently, academics, practitioners, and policy makers have very little empirically based guidance for their engagement activities, with scant empirical evidence to choose or eschew involvement elements and approaches (Rowe & Frewer, 2000, 2005). Are educationally oriented communications critical prior to an engagement, or is it sufficient to provide them at the event? Should communications follow some specific approach, or are any informational materials okay so long as they are geared for adult learners? If it is not good enough to rely on surveys for policy-making input, should consensus conferences, citizen juries, or deliberative discussions be used? Is it more effective for participants to interact face-to-face, or does online engagement suffice or have benefits that face-to-face interactions do not? Does there even have to be an engagement, or would a simple opportunity to provide input after being adequately informed result in useful policy contributions? Unfortunately, the numerous calls for public engagement do not answer such questions nor do they specify *which* public engagement efforts are appropriate or effective for different purposes.

The Challenges: Determining Which, for What, and Why

The literature suggests three broad challenges face the social science of public participation: defining and determining (*which*) key features and dimensions upon which public participation activities vary are important; defining and determining major purposes of public engagement by which (*for what*) “effectiveness” should be

evaluated; and developing new models that explain how (or *why*) variations in public participation methods are causally connected to variations in effectiveness.

Which: Developing Taxonomies and Dimensions of Public Participation

Past attempts to simplify the plethora of public engagement types, mechanisms, and features have categorized types of engagement according to numerous characteristics including their different objectives, structural characteristics, inherent problems or limitations, functional attributes, extent or level of participation, information flow, ability to empower, or philosophical underpinnings (Renn & Schweizer, 2009; Rowe & Frewer, 2000, 2005). However, differing on one of these dimensions does not preclude different engagement mechanisms from differing on other dimensions as well, making it difficult to confidently point to specific features (or factors separate from the engagement altogether) that are responsible for inconsistent results when comparing two or more engagements.

The answer to the challenge of pinpointing “which” features of public engagement are effective for *what* may have an obvious answer: controlled experiments. Controlled experimental research can specifically vary certain features more narrowly and test for effects. Unfortunately, the “answer” of experiments raises two additional questions: which features should we test and (perhaps even more frequently lamented) will our results be generalizable outside of experimental contexts?

The issue of generalizability may be partially addressed by collaborations between researchers and practitioners such that experimental research is conducted in actual participatory contexts. Not all research questions can be examined this way, but some can. For example, in one of our research studies, within an actual public engagement, we randomly assigned slightly different deliberation instructions to small groups: some were asked to come to consensus on their recommendations, and others were told to form their individual opinions and then vote. Although the results of this study may or may not be generalizable to different content contexts, the results are more likely to be generalizable to discussions of city government and budgeting because the experiment took place in that actual applied context.

Setting aside the issue of generalizability, another drawback of experiments is that they are painstaking and seemingly inefficient. Carefully controlled experiments typically vary a small number of features at a time, whereas the possible features varying naturally in public engagements are myriad. The thought of systematically and experimentally testing thousands of variants is likely to make one beg for a shortcut. The need to simplify and focus on a limited number of variables within complex environments is, of course, a general challenge in social psychology and has resulted in attempts to develop situational taxonomies (e.g., Cantor, Mischel, & Schwartz, 1982; Reis, 2008; Ten Berge & De Raad, 1999). In light of such efforts, we propose three starting points or strategies that public engagement researchers may employ to narrow their focus and productively choose from the vast array of possibilities:

Start with what is: experimentally vary what is most commonly naturally varied or that which has implications for cost effectiveness. Two often-referenced variations include

methods that engage individuals versus groups (e.g., individual survey responses vs. group discussion within deliberations) and those that vary in their objectives (e.g., education vs. consultation) and thus also in their cognitive demands (i.e., to learn vs. to offer useful input that holds up under critical evaluation) (Lewenstein & Brossard, 2006). Other common variations include online versus face-to-face engagements, with online engagements typically costing less to conduct.

Start with what should be: vary the features most likely to impact engagement effectiveness. This perspective is endorsed by researchers such as Rowe and Frewer (2005), who noted that features impacting effectiveness are the most important variables in need of study. It is also consistent with efforts in social psychology to create situation taxonomies specific to certain outcomes, such as classes of situations that allow variation in certain personality traits to be observed (Ten Berge & de Raad, 1999).

While use of this second strategy suggests that the importance of variables in terms of their impact on effectiveness needs to have been established empirically, a third strategy can assist researcher choices while empirical research is underway: *vary features suggested by theory*. This is perhaps the most common approach in psychology: psychologists tend to vary a narrow few but often powerful situational factors in isolation or combination in order to better understand the scope and contingencies of their effects. These second and third strategies relate to questions of “for what?” and “why?” so we expand on them later.

For What: Defining “Effectiveness”

A second challenge to advancing the social science of public participation is to define “effectiveness.” In the public participation literature, calls for public engagement arise in part out of theoretical expectations of numerous benefits, including the promotion of democratic values (e.g., Ackerman & Fishkin, 2004; Chambers, 2003; Elster, 1998; Fishkin, 1997; Gastil, 2000), enhanced social trust (Price & Cappella, 2002), increased sophistication of political and social reasoning (Muhlberger, 2006), reduction of conflicts, and identification of common values and areas of policy agreement (e.g., International Risk Governance Council, 2007). All of these benefits might be viewed as indicators of effectiveness. Although opinions may differ on the most important indicators of the effectiveness or success of a public engagement exercise, there is some consensus that defining effectiveness should be performed in relation to the goals of a public engagement endeavor (Rowe & Frewer, 2004). However, within nanotechnology, and paralleling the general public engagement literature, engagement efforts often aim for multiple, and oftentimes, competing goals (Abelson et al., 2003). For example, it has been suggested that successful nanotechnology–ELSI engagements would increase public knowledge of nanotechnology, public trust in regulation of nanotechnology (Macoubrie, 2005), the perceived legitimacy of nanotechnology-related decisions (McComas, Besley, & Yang, 2008), the quality of input to policy making, and the quality of policy decisions themselves (Farrelly, 2007). However, it may be that increases in one criterion (e.g., citizen knowledge) has a detrimental impact on other criterion (e.g., public trust) (cf. Stirling, 2006; Wiedemann & Schutz, 2005; but see Macoubrie, 2005).

Given the number of potential effectiveness criteria that might be considered, the best strategy for moving forward is likely to be to accept and operationalize “effectiveness” as a set of constructs, many of which are multidimensional. Though values and ideals (which different people will value differently) must be considered in making the final choices concerning the relative importance of effectiveness criteria, a useful starting place is to consider them by category or type. As pointed out by others (e.g., Abelson et al., 2003; Chess & Purcell, 1999; Rowe & Frewer, 2004), effectiveness criteria can be categorized as follows: *representation criteria*, relating to the extent to which persons invited and involved are appropriately representative of all stakeholder groups (e.g., were people included from different interest groups, geographic regions, and political viewpoints, and were both layperson and nanotechnology expert views considered?); *process criteria*, relating to the extent to which procedures result in effective processes (e.g., during the engagement, did activities result in relevant discussion, accurate information exchange, inclusion of the diverse views and voices that were present?); and *outcome criteria*, relating to the products of the engagement (e.g., is the policy input obtained from the engagement competent and pertinent? Did it improve policy decisions?). Two additional criteria, sometimes categorized as process criteria, are also relevant: *information criteria*, relating to the selection, presentation, and interpretation of information and *acceptance criteria*, relating to the extent to which the public finds the engagement activities appropriate and useful (e.g., does the public view the activities as fair, democratic, worthwhile?).

As shown in Figure 1, these effectiveness criteria roughly map to the general steps involved in planning and executing a public engagement. By considering the relationships between such steps and the effectiveness criteria, researchers may be able to better focus their empirical questions on certain parts of the public engagement process. Thus, lines of research could be constructed to link methods of information selection and preparation to perceptions of that information within the context of various public engagements. Other lines of research might link methods of stakeholder selection and recruitment to representativeness criteria. Lines of research might focus across the different phases of public engagement as well. For example, do different methods of information selection and construction impact perceptions of processes differently? For example, it could be that different forms of information (e.g., expert- vs. citizen-selected information) are viewed as more acceptable by participants when used in online deliberations than when used in face-to-face deliberations.

Note that the alignment of effectiveness criteria with the various decision points associated with variation in public engagements does not narrow or limit the number of effectiveness criteria overall. Rather, it organizes those criteria in a manner that suggests directions for moving forward and beginning to strategically map out a plan for experimental investigations of public engagements. However, there are other potential ways of organizing effectiveness criteria that may also be fruitful. For example, it may also be useful to consider the *psychological nature* of the various effectiveness criteria. The observation that some effectiveness criteria are essentially cognitive in nature (e.g., learning outcomes) and others largely affective (e.g., satisfaction) can suggest different useful *theoretical* perspectives associated with different effectiveness criteria. Various theories of *cognitive* engagement, for

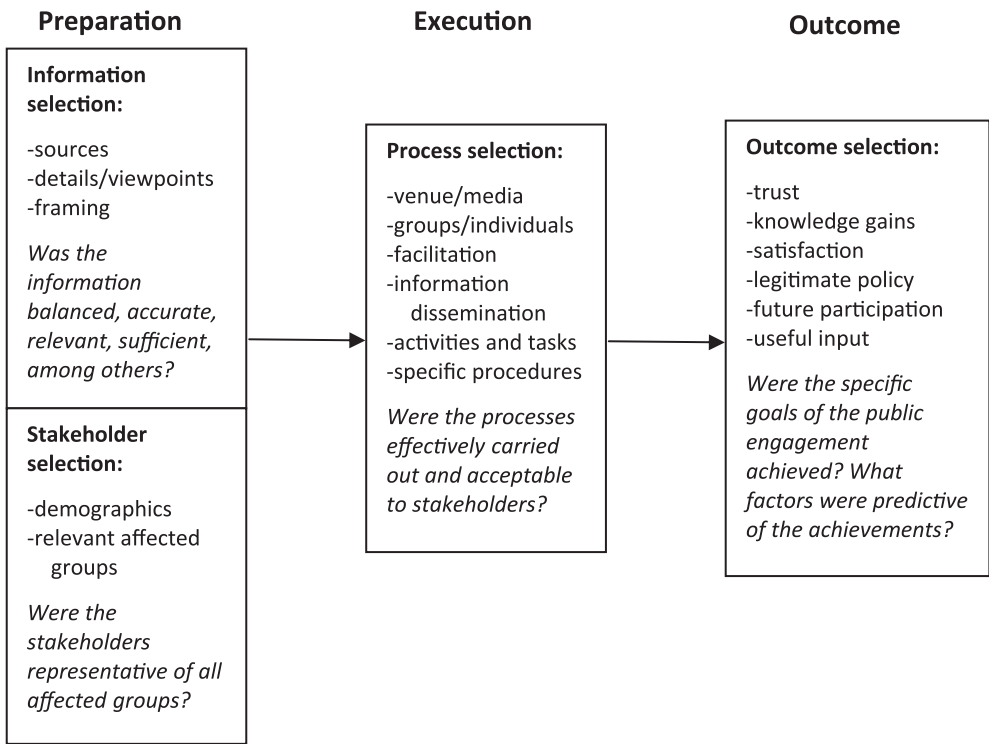

Figure 1. Relationships between Effectiveness Criteria and Phases of Planning and Executing a Public Engagement

example, can be used to predict, promote, and understand *learning* gains from engagement activities.

Why: A Need for Better Theoretical Models

The ultimate challenge, a challenge that to fully meet requires defining the important features of participatory activities and the effectiveness criteria by which they should be evaluated, is to develop better theoretical models explaining the causal connections between those engagement features and effectiveness criteria. Currently, some theoretical benefits are supported (but not explained) by studies documenting positive outcomes (for reviews, see, e.g., Chilvers, 2008; Delli Carpini et al., 2004). For example, participating in engagement activities has been found to be enjoyable and educational for members of the public (Powell & Kleinman, 2008) and to stimulate further discussions with friends and family members beyond the formalized engagement setting (Besley, Kramer, Yao, & Toumey, 2008), as well as resulting in increases in knowledge, opinion sophistication, high levels of satisfaction (e.g., Barabas, 2004; Gastil & Dillard, 1999; Luskin, Fishkin, & Jowell, 2002), and positive influences on strategic decision making (e.g., Muhlberger, 2005). However, at the same time, there is contradictory theory and evidence to suggest public engagement endeavors can result in negative outcomes (e.g., Delli Carpini et al., 2004; Sunstein, 2005), such as participant dissatisfaction (e.g., Karpowitz & Mansbridge, 2005; Mansbridge, 1983; Mendelberg & Oleske, 2000; Smith & Wales,

2000) and group conflict and polarization (e.g., Kuran & Sunstein, 1999; Mendelberg, 2002; Spears, Lea, & Lee, 1990; Sunstein, 2002; Walsh, 2006). In addition, in some circumstances, making decisions in groups does not increase decision accuracy but rather encourages people to solve problems at the level of the average member of the group (e.g., Barron, 2003; Gigone & Hastie, 1997).

In light of the interests in the use of public engagement in the creation of science and technology policy, the many public engagement options available, and the inconsistent outcomes obtained from public engagement endeavors, it has been observed that “a public participation taxonomy [or model] that recommends which form of public participation to use in a particular situation” would be most welcome, especially for practitioners designing such activities; however, the existing “empirical data are not sufficient to do so with confidence” (Chess & Purcell, 1999, p. 2690; see also, Rowe & Frewer, 2005). Despite the decade that has elapsed since Chess and Purcell’s lament, little progress has been made in the systematic and purposeful accumulation of empirical data that would allow for the construction of such taxonomies or models.

This is not to say that there have not been many suggestions concerning features that should be included in public engagement or which may enhance “successful” participation. As Rowe and Frewer (2004) noted, “[c]ertainly, there are copious suggestions in the literature about participation-exercise effectiveness, but few, if any, formalized and detailed theories” (p. 543). Commentators have called for engagement concerning nanotechnology that is transparent, open-ended, and based on the genuine willingness of policy makers and other decision makers to involve and engage the public (Powell & Colin, 2008). In addition, general theoretical frameworks for conceptualizing the design and goals of public participation and engagement have evolved over the last couple of decades, moving from reliance on *deficit models*, which portray the goal of public participation as correcting the public’s lack of scientific knowledge (Ziman, 1991, 1992), to other models that suggest the need to also take into account factors such as public values and contexts (*contextual models*; e.g., Wynne, 1996), local expertise and knowledge of affected citizens (*lay expertise models*; e.g., Ellen & Harris, 1996; Wynne, 1996), and opportunities for direct engagement (*public engagement models*; e.g., Hamlett, 2002; Wachelder, 2003).

These common theoretical frameworks, and others such as Rowe and Frewer’s (2005) *information flow model*, focus on the knowledge and learning processes involved in public engagement, and the learning and understanding that can be gained by policy makers who receive informed, high-quality, public input. However, as noted by Lewenstein and Brossard (2006), these models do not capture the complexity and diversity of actual science education and public engagement efforts (see also Brossard & Lewenstein, 2009). In addition, the models fail to causally connect specific, key features of public participation to the various documented positive effects associated with participation activities (Rowe & Frewer, 2000, 2004, 2005).

Theoretical advancement may not be too far away—a number of social, psychological, and other theories are already implicitly or explicitly referenced by current perspectives on public engagements. A broader consideration of these theories, especially in developing experimental hypotheses relevant to different features of

public engagement or relevant to specific effectiveness criteria, could both expand and clarify current models. For example, especially relevant to deficit and contextual models of public engagement are cognitive theories of knowledge transfer, which over time, gave way to social constructivist theories of learning (McKeachie, 1990; Nix, Fraser, & Ledbetter, 2005). Contextual engagement models also include many of the tenets of situated learning theories (e.g., Brown, Collins, & Duguid, 1989), and they attend to participant attitudes as well, making attitude theories from social psychology relevant (e.g., Ajzen, 2001). Social theories and research on persuasion (Murphy, Holleran, Long, & Zeruth, 2005; Tormala & Petty, 2004) and risk perception and risk-seeking or risk-avoidance tendencies (Kahlor & Rosenthal, 2009; McCauley, 1972) are also germane. The application of such theories to public engagement contexts could advance both public engagement theory and applied social scientific theories.

The Future of Public Engagement Social Science

As our *which*, *for what*, and *why* analysis suggests, major barriers to the advancement of the social science of public engagement in general (see especially, Rowe, Horlick-Jones, Walls, Poortinga, & Pidgeon, 2008), and the problems that impede successful public contributions to nanotechnology policy in particular, include the following: the large diversity of approaches within and across engagement practices; the lack of agreement on definitions of “effective” engagement, whether the focus is on the public participants or the policy makers or in the case of scientists, others who might use the input; and the lack of theoretical or empirical attention to the reasons why or mechanisms by which certain public engagement features appear to connect to various outcomes.¹ Earlier, we suggested some general ideas concerning dealing with these barriers including applying strategies for identifying features of public engagement worthy of experimental examination, focusing on various effectiveness criteria that relate to specific preparation and execution phases of engagement, and appropriately applying well-established theories from other fields, especially from social and learning sciences, in order to advance theoretical understanding of public engagement activities and outcomes. We propose that application of these general ideas would lead to a future social science of public engagement that is grounded in theory buttressed by empirical, even experimental, evidence.

Next, we describe one such application of these ideas (though there could be many) that has guided our current research involving nanotechnology public engagements.² We started from the previously mentioned observation that two often-referenced variations in public engagement activities include methods that engage individuals versus groups and those that vary in their objectives or desired outcomes. Our very general hypothesis was that these *features* of public engagements will change individual- and group-level mediating *processes*, resulting in different impacts on individual, scientific, and policy *outcomes* commonly used to evaluate the effectiveness of engagement efforts. Figure 2 gives examples of such features, processes, and outcomes and illustrates a simple and flexible overarching framework. Though our framework is a preliminary one, and there are likely to be many other possibilities, such frameworks are useful “maps” that can guide research

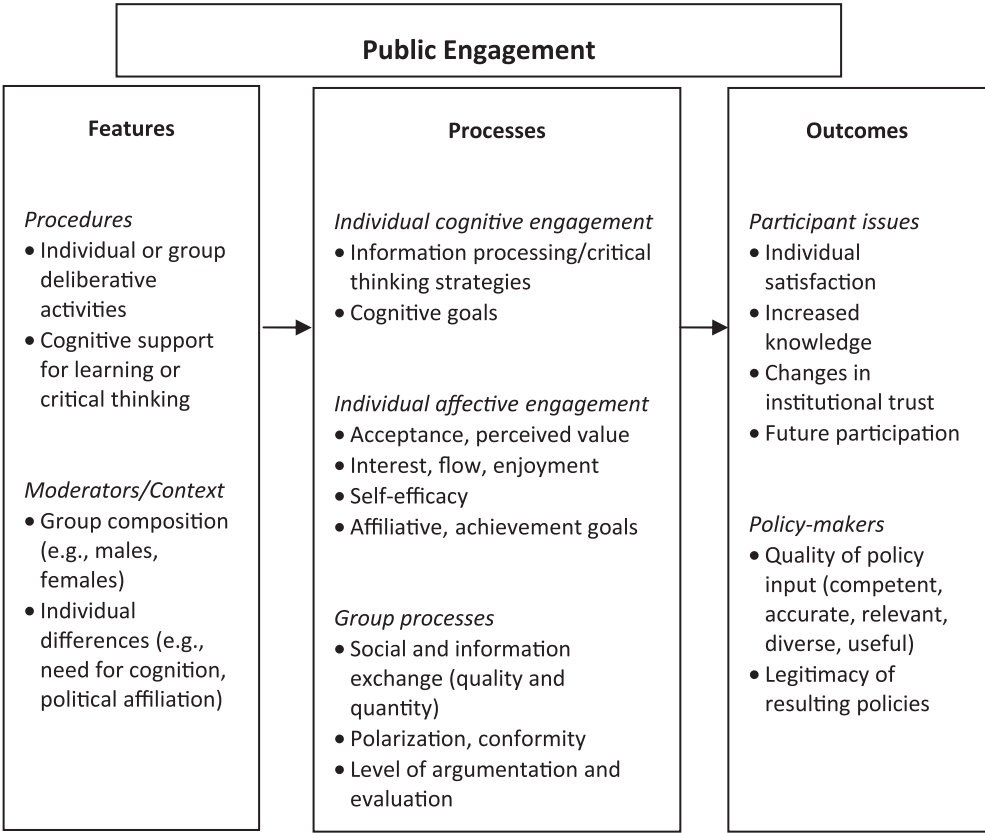

Figure 2. Example Framework for Investigating Public Engagement in Science and Innovation Policy (e.g., Nanotechnology)

(and even engagement efforts themselves) by outlining the many possible areas of focus.

We developed this framework by analyzing our two targeted features of public engagement (social context and purpose), through the broad lens of multiple, social-cognitive psychological (including learning) theories. We used such theories to guide our efforts to understand why and under what conditions these differing participation features might lead to different processes and outcomes. Consistent with social-cognitive theories, we also considered theories of *engagement* (e.g., as reviewed by Fredricks, Blumenfeld, & Paris, 2004), which, similarly, point to the manner in which learning environments and contexts impact diverse educational outcomes via cognitive, affective, and behavioral engagement (Newmann, Wehlage, & Lamborn, 1992). These social-cognitive and engagement perspectives, therefore, each suggest useful mediators and methods for assessing various forms of engagement and outcomes during public engagement exercises.

In the research we currently are conducting, use of this framework directs us to attend especially to the cognitive aspects of public engagements. For example, engagements designed to educate and inform imply the need for participants to learn; engagements designed to gain critical public input imply the need for participants to think critically. Thus, narrower social-cognitive models of

collaborative learning and *critical thinking* are especially relevant to understanding and making hypotheses concerning the effects of social context (group vs. individual) and purpose (inform vs. consult) public engagement features (Anderson, Howe, Soden, Halliday, & Low, 2001; Guiller, Durndell, & Ross, 2008; Halpern, 2007; Moon, 2008; Norris, 1992; Pithers & Soden, 2000; Wickersham & Dooley, 2006). Consideration of these theories led us to a number of hypotheses, including that group discussion will facilitate numerous dependent variables (mediators and outcomes), such as participant engagement, factual learning, and quality of critical thinking concerning issues. Our rationale is that peer interaction in collaborative learning has been found to facilitate factual learning when peers can share information on strategies that are provided for that learning (Willoughby, Wood, McDermott, & McLaren, 2000).³ In further support of the benefits of discussion, Levin's (1995) qualitative comparison of the effects of reading and writing concerning case studies versus additionally discussing them found that those in discussion conditions were more likely to elaborate on their original ideas, whereas those who worked alone tended simply to consolidate their original ideas (see also Flynn & Klein, 2001). Meanwhile, others have found that elaboration of ideas significantly increases learning (Willoughby et al., 2000). Others have noted that peer discussion generally requires and enhances engagement (Levin, 1999; Thomas, 2002) and can facilitate critical thinking by challenging students' assumptions, emphasizing analysis and evaluation, and providing practice in critical thinking and listening (McDade, 1995).

Consideration of additional theories led us also to hypothesize that provision of supports for critical thinking will have additional benefits beyond those afforded from supports for learning. Especially relevant to this hypothesis is Freire's Empowerment Education Model (e.g., Freire, 1970/1993) and its recent expansion. Freire's model includes three components or phases for empowering participants: listening, dialogue, and action (Schugurensky, 1998). Recently, however, others have proposed that effective public engagement requires going beyond dialogue and the creation of understanding (i.e., learning goals) to include deliberation (i.e., critical thinking goals) concerning various options as an explicit part of the decision-making process (Downey, Anyaegbunam, & Scutchfield, 2009; Wallerstein & Sanchez-Merki, 1994). The need to explicitly engage citizens in critical thinking, as well as learning goals, is an important but relatively neglected part of public engagement that we thus chose to include as a focal point of our studies. The foundation of critical thinking is accurate knowledge that is then manipulated and applied in evaluating, comparing, and contrasting choices when making decisions. Although learning and critical thinking exercises may contribute similarly to factual learning, critical thinking supports, especially with peers, may also enhance engagement and the production of higher quality problem analyses and superior input.

Conclusion

We are faced with a number of challenges in order to effectively meet the commitment to effective public participation in the context of nanotechnology, in particular, or in other areas of science and innovation. These challenges arise from the

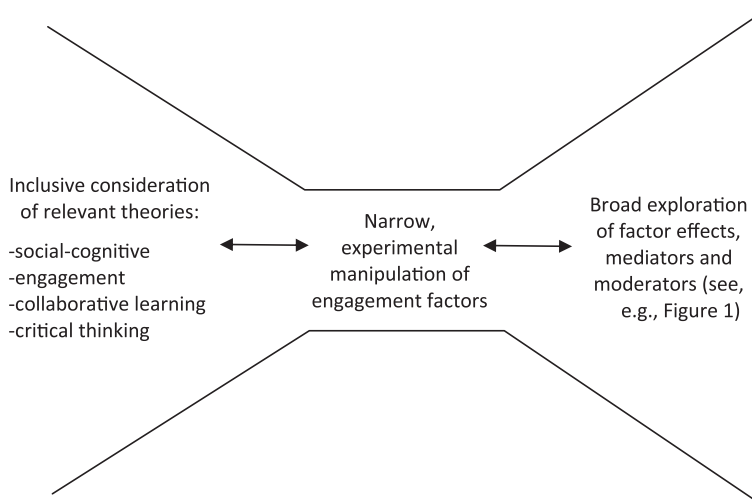

Figure 3. Research Approach for Studying Public Engagements

complexity of the task and from the lack of prior systematic empirical research identifying and then connecting important features of public participation engagements to well-defined and valued effectiveness criteria. Given this lack of prior work and the large number of variables that might vary among different types of engagement activities, it will be important for science research funders to support inquiries that might, under other circumstances, be viewed as too ambitious in the number of variables explored or even criticized as “fishing expeditions.” Complex research designs, such as fractional factorial designs (Gunst & Mason, 2009), would be promising methods for conducting such research, but many other research approaches are also possible.

In addition, because it is easier to reach goals that are clearly identified than those that are not, we are challenged to consider and carefully define the purposes and the criteria by which public engagements should be evaluated *at different phases of policy development and implementation*. Are the same techniques that are useful for consideration of policy issues that are time-limited (e.g., H1N1 flu vaccine prioritization: see Bulling & DeKraai, in press; DeKraai & Bulling, in press) different than ones that are long term and involve the complicated interrelationships of science, technology, workforce exposure, and public safety (e.g., nanotechnology manufacturing; nanofoods)? What might be useful when controversial moral, religious, social, and ethical values are involved, such as in the case of stem cell research or the use of biobricks to create or modify living cells? Are different goals involved, and thus, different methods of public input, appropriate for considerations of science and technology that are just evolving as opposed to goals we want to posit for science and technologies that are more mature? Figure 3 provides a proposed, iterative approach for use in a program of research to address these empirical questions.

These are, at heart, public issues. Perhaps, the public itself should be involved in identifying the applicable criteria. We have documented that public engagement increases confidence in government (Tomkins, PytlikZillig, Herian, Abdel-Monem,

& Hamm, 2010). However, although we know *that* trust and confidence increases, we do not know which forms of public engagement are superior for such purposes and why. In any event, until more is known concerning the manner in which different participatory features affect results of public engagements, it would be wise to use multiple types of participation for comparison purposes and evaluate processes and results not only for the benefit of systematic social science but also for optimal governance.

Finally, it is important to note that in this article, we have outlined in broad-brush form only a few of the important challenges. As the challenges we have identified are addressed, other challenges will become apparent. For example, developing models and measures is a circular process whereby theory is needed to establish measures and measures are needed to test the tenets of the models under development. Thus, another challenge to model-building efforts in the area of public engagement in science and technology policy is the lack of agreed-upon operationalizations and standardized measures for assessing various effectiveness criteria (Rowe & Frewer, 2004; Rowe et al., 2008). Upon identifying important effectiveness criteria, as well as important features and dimensions of public participation, there will be a need for reliable and valid measures of those constructs.

Policy makers around the globe entice us with the promise of open, transparent, participatory, and collaborative government. There are contributions we believe social science can make to advance this important initiative. We are humble yet hopeful: as social scientists, we know that we know very little, we realize we need to know a lot more, and we are confident that through rigorous experimental studies and systematic programs of research, such knowledge can be gained (see, e.g., Currall, 2009). We have examined these issues in the context of nanotechnology, but the need to have “an honest conversation [by scientists] with the public about what they are doing and why” (Rejeski, 2009, p. 13) is as germane to genetic engineering policy (Cox, Kazubowski-Houston, & Nisker, 2009; Cox & Nisker, 2010; Nisker, Cox, & Kazubowski-Houston, 2006; Specter, 2009) as it is to nanotechnology policy. As social scientists *and* as citizens, we call for and value social science research on engagement practices because of the hope it offers for realizing the promise of a more transparent, participatory, and collaborative government—a promise that is at the heart of the democratic ideal and sound science and innovation policy.

Notes

- 1 One could also add other barriers, such as the lack of standardized, reliable measures of engagement processes and effectiveness criteria upon which to compare different forms of engagement. Here, however, we focus primarily on the three listed.
- 2 This research is currently being conducted as part of a project, “Developing a Social-Cognitive, Multilevel, Empirically-Based Model of Public Engagement for the Shaping of Science and Innovation Policy,” with funding from the National Science Foundation (SBE-0965465).
- 3 Some public engagement research has not found increased factual learning that can be attributed to group deliberation rather than information provision (e.g., Muhlberger & Weber, 2006). However, we reason that this may be because while public engagement activities often aim to inform citizens and/or seek citizen input, these engagement activities usually do not teach participants *strategies* for learning that information or thinking critically concerning the information so they can provide more valuable input.

Acknowledgments

About the Authors

Lisa M. PytlikZillig is a researcher at the Public Policy Center at the University of Nebraska, and at the Center for Instructional Innovation at the University of Nebraska-Lincoln. Her research includes public engagement, institutional confidence, use of science information in policy and other decisions, and use of technology to enhance education and engagement.

Alan J. Tomkins directs the University of Nebraska Public Policy Center. His research interests include public input to and public trust and confidence in government, public engagement to inform science policy, and issues of justice and fairness.
